

CUSTOM RATES

for Idaho Agricultural Operations 2010–2011

by Paul E. Patterson and Kathleen Painter

The Authors

Paul E. Patterson and Kathleen Painter are both agricultural economists with the Department of Agricultural Economics and Rural Sociology, University of Idaho.

Acknowledgments

The authors appreciate and would like to acknowledge the cooperation of the farmers, custom operators, and other agribusinesses that willingly took part in the survey upon which this publication is based. We would also like to acknowledge and thank Pat Norell for her contributions in collecting and summarizing data.

In addition, extension educators or their office staff provided us with the names of many custom operators and assisted us with data collection, including: William Bohl (Bingham County), Danielle Gunn (Fort Hall), Donna Gillespie (Minidoka County), Cindy Kinder (Camas County), Ruhn Panting (Oneida County), and Jo Ann Robbins (Jerome County). Special thanks go to the southern Idaho Cereal Schools for providing funds for the printing of this publication.

CUSTOM RATES 10-11

for Idaho Agricultural Operations

The primary purpose of this publication is to report data obtained by a survey of custom operators in Idaho. It also provides information on how to calculate machinery costs for setting custom rates, as well as how to adjust historical custom rates using indices available from the United States Department of Agriculture (USDA).

The equipment needed for a modern farming operation is expensive and often quite specialized. On a smaller farm, it may be impractical to own all of the necessary equipment. Even a large farm with a complete machinery complement may find it necessary to use a custom operator or to hire a neighbor to avoid missing a planting or harvesting window when weather delays occur.

A custom operator typically specializes in certain farm operations, whereas a neighbor simply may have the equipment and time to trade work or to provide services for a fee. Some specialized farming operations use their equipment to do custom work during “slack times” on their farm or ranch. This can reduce ownership costs and provide needed cash flow.

The question that arises is how much should be charged or paid for these services. Full-time commercial custom operators should charge a fee that covers all machinery and labor costs plus a profit. Those performing custom services for a neighbor might charge only enough to cover labor and fuel costs.

In areas where a considerable portion of farm work is done by custom operators, established customary rates cover actual machine operating and ownership costs. Problems can arise, however, where no customary rates have been established or when a rapid increase in costs puts established rates significantly below total costs. This publication can help custom operators and growers calculate appropriate custom rates in such circumstances.

Idaho Geography

Idaho varies greatly in topography, climate, soils, and other variables affecting agricultural production. Consequently, a wide variety of crop/livestock enterprises and management systems exists. Because of this variability, production costs can differ from one area to another and even between adjacent farms or ranches.

Custom rates reported in this publication are tied to four geographic regions of Idaho. These regions no longer correspond to administrative boundaries for Extension Districts as they did in previous versions. Counties are placed in the region with the most similar type of production agriculture. For example, Blaine and Camas counties are included with the eastern Idaho counties and not with the Magic Valley counties of southcentral Idaho. Boldface type indicates the counties where the majority of survey respondents were located.

- **Northern Idaho** covers Benewah, Bonner, Boundary, Idaho, Kootenai, Latah, Lewis, and Nez Perce counties.
- **Southwestern Idaho** covers Ada, Adams, Canyon, Elmore, Gem, Owyhee, Payette, and Washington counties.
- **Southcentral Idaho** covers **Cassia, Gooding, Jerome, Lincoln, Minidoka, and Twin Falls** counties.
- **Eastern Idaho** covers **Bannock, Bear Lake, Bingham, Blaine, Bonneville, Butte, Camas, Caribou, Clark, Custer, Franklin, Fremont, Jefferson, Lemhi, Madison, Oneida, Power, and Teton** counties.

Because of insufficient precipitation, irrigation is essential to crop production in most parts of the Snake River Plain that extends across southern Idaho. Farming practices, field size and shape, and types of equipment are influenced by irrigation in these areas. Although farming practices are comparable across much of the irrigated portions of southern Idaho, there are some regional differences, particularly in southwestern Idaho, where smaller fields translate into higher machinery operating expenses.

Rain-fed agriculture is dominant in the cooler northern Idaho region, where climate patterns affect crop choice, production practices, and equipment. However, northern Idaho does share some cultural practices and machinery types with the dryland grain-producing areas of eastern and southern Idaho.

Owning vs. Custom Hire

Custom services can sometimes be hired at a cost lower than that of owning and operating farm equipment, particularly on smaller farms. For example, a new grain combine that costs \$320,000 will have an annual ownership cost of \$40,000 or more. If operating costs for this combine are \$14 per acre and a custom operator charges \$35 per acre, then a minimum of 1,905 acres of grain must be harvested before ownership becomes as economical as hiring a custom operator.

The breakeven acreage calculation uses the following formula:

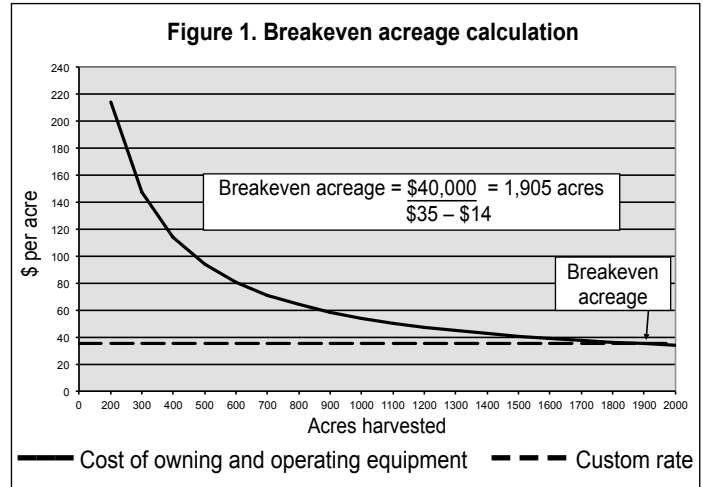

$$\text{Breakeven acreage} = \frac{\text{Annual ownership cost}}{(\text{Custom rate per acre} - \text{Operating cost per acre})^1}$$

Annual ownership cost	=	Annual depreciation, interest, taxes, insurance, and housing (see Table 1 [page 6], line 9)
Custom rate per acre	=	Going rate charged for that service (see Tables A–M)
Operating cost per acre	=	Fuel, maintenance and repairs, labor, and supplies (see Table 1 [page 6], line 17)

¹The same calculation can be done if costs are given per mile, bale, cwt, or some other unit, rather than per acre.

Figure 1 is based on this breakeven calculation. It shows that the cost of owning and operating the grain combine is greater than the cost of custom hiring up to the breakeven acreage (1,905 acres). If the owner of the equipment uses it on more acres than the number needed to break even, the average cost per acre will be less than the amount required to hire a custom operator.

Breakeven cost calculations should be based on both cash and non-cash costs. Non-cash costs include

owner-operator’s labor, depreciation, and interest on the owner’s equity. Cash costs are the more obvious ones, such as fuel, maintenance and repairs, hired labor, taxes, and interest paid on equipment loans. See “Calculating Machine Costs” (page 5) for more information about calculating annual ownership cost and operating cost per acre. Table 1 (page 6) is an example of a cost calculation using an example of plowing.

Other considerations include the availability of custom operators and their timeliness in completing the work. Crop yield and quality may suffer if the custom operator cannot complete tillage, spraying, planting, or harvesting operations in a timely manner. The quality of the custom work should also be considered. Each farmer needs to determine the risk associated with timeliness and quality of work. These risks vary by crop, location, financial condition of the farmer, and competition in the custom services market.

Survey Data

From November 2010 to April 2011, custom operators, farmers, and other agribusiness firms in Idaho were contacted about custom rates charged or paid for various farm operations. Names were obtained from extension agricultural educators, classified sections of newspapers, commodity directories, other farmers, and custom operators. Respondents were contacted by telephone or by mail. Some respondents provided the rates they charged in 2010, while others provided their 2011 rate schedule. It should be noted that fuel prices jumped substantially from the time the survey started until it was completed.

Previously published Idaho Custom Rates Guides organized data by region. This publication departs from that practice. Instead it organizes southern Idaho data

by the type of field operation and shows the responses by region and for the southern Idaho average. Tables A through L present the southern Idaho data. Data for northern Idaho are presented in Table M.

Tables A–M show the average, high, and low custom rate charge reported, as well as the number of responses. Unless noted otherwise, costs of materials such as chemicals, seed, and fertilizer are not included in the custom rates quoted.

The thirteen tables located in the Appendix are listed below.

Table A. Custom aerial application costs: Dry and liquid materials, 2010–2011 (Southern Idaho)

Table B. Custom ground application costs: Dry and liquid materials, 2010–2011 (Southern Idaho)

Table C. Custom row markout (bedding) and fumigation costs, 2010–2011 (Southern Idaho)

Table D. Custom tillage costs, 2010–2011 (Southern Idaho)

Table E. Custom cultivation costs, 2010–2011 (Southern Idaho)

Table F. Custom planting and seeding costs, 2010–2011 (Southern Idaho)

Table G. Custom harvesting costs for hay, peas, and straw, 2010–2011 (Southern Idaho)

Table H. Custom harvesting costs for silage and other forage crops, 2010–2011 (Southern Idaho)

Table I. Custom harvesting costs for dry beans, dry peas, seed crops, corn, and small grains, 2010–2011 (Southern Idaho)

Table J. Custom harvesting costs for onions, potatoes, and sugarbeets, 2010–2011 (Southern Idaho)

Table K. Custom hauling costs, 2010–2011 (Southern Idaho)

Table L. Miscellaneous custom operation costs, 2010–2011 (Southern Idaho)

Table M. Northern Idaho rates for custom work and equipment rental, 2010–2011

Calculating Machine Costs

Where information about custom operations and rates is not available, one may need to calculate the cost of performing a particular task. Machine costs can be separated into time-related and use-related categories. Time-related expenses may be classified as ownership costs, while use-related costs may be referred to as operating costs. As might be expected, machine costs do not always fall neatly into a particular category. For example, depreciation is a function of both time and

use. For clarity, this publication follows the traditional conventions of classifying costs as shown below.

Ownership costs:

- Annual depreciation
- Interest on the value of the machinery and equipment
- Property taxes on the machine (if applicable)
- Insurance
- Shelter or housing

Operating costs:

- Fuel and lubrication
- Maintenance and repairs
- Supplies used in the operation (e.g., baler twine)
- Labor

Equipment costs vary by farm and by custom operator. Factors that influence equipment costs include operating conditions, amount and type of equipment use, original cost of the machinery, replacement costs, interest rates, and quality of maintenance, among others.

The method for estimating machinery costs is the same for both new and used machinery. The parameters are different, however, and the resulting cost per hour of operation may differ significantly.

Producers' machinery records are the best source for cost information. However, if records are lacking, one can make a cost estimate as shown in Table 1 (page 6). The moldboard plow example in Table 1 shows that costs must be calculated separately for the tractor and plow; the tractor is used for a different number of hours, and the tractor and plow have different cost factors and different rates of depreciation. Note that labor is charged only once because only one operator is needed for both pieces of equipment. Be sure to add the cost of materials, such as chemicals, seed, twine, fertilizer, etc., when these are provided by the custom operator.

In this example, the tractor's hourly cost is \$81.00, and the plow's hourly cost is \$15.90, for a total of \$96.90 per hour for the plowing operation. If 2.8 acres are covered per hour, the cost per acre is about \$34.60 ($\$96.90 \div 2.8$).

Acres covered per hour can be estimated based on personal experience or by using the following formula:

$$\text{Acres per hour} = \frac{[\text{Speed (mph)} \times \text{machine width (ft)} \times \text{machine's field efficiency (\%)}]}{8.25}$$

For example, if a 16-foot-wide machine travels at 4 miles per hour and has a field efficiency of 70 percent, the calculation would be as follows:

$$\frac{[4 \text{ mph} \times 16 \text{ feet} \times 0.70]}{8.25} = 5.4 \text{ acres per hour}$$

Typical speeds and field efficiencies for various types of machinery are shown in Table 2 (page 7). Field efficiency is less than 100 percent because of equipment overlap, turning time, and time required to adjust and service machinery and to fill hoppers and tanks when inputs are being applied.

One reference for estimating machinery costs is PNW Extension publication 346, *The Costs of Owning and Operating Farm Machinery in the Pacific*

Northwest (University of Idaho, 2011). Estimates in this publication are based on new machinery costs and a range of expected total hours of use during the life of the machine.

Another useful tool is *Machinery Cost Analysis*, a University of Idaho Windows-based computer program available from the UI Department of Agricultural Economics and Rural Sociology website (see “References and Other Useful Links,” page 10).

Table 1. Estimating costs of owning and operating farm machinery, using an example of plowing.

Equipment parameters	165-hp tractor	4-bottom (plow)
1. Purchase price ¹	\$130,000	\$12,000
2. Expected ownership period (years) ²	15	10
3. Salvage value ³	\$25,000	\$2,000
4. Adjusted average value ⁴	\$81,000	\$7,500
5. Estimated annual hours of use	500	150
Annual ownership cost		
6. Depreciation ⁵	\$7,000	\$1,000
7. Interest ⁶	\$4,860	\$450
8. Taxes, housing, and insurance ⁷ (see Table 3, page 8)	\$891	\$38
9. Annual ownership cost (line 6 + line 7 + line 8)	\$12,751	\$1,488
10. Ownership cost per hour (line 9 ÷ line 5)	\$25.50	\$9.92
Annual operating cost		
11. Repairs and maintenance per hour ⁸	\$10.80	\$6.00
12. Fuel consumption: gallons per hour ⁹	7.25	–
13. Fuel and lubrication cost per hour ¹⁰	\$27.10	–
14. Labor (\$16.00/hr x 1.1) ¹¹	\$17.60	–
15. Materials needed (twine, etc.) ¹²	–	–
16. Total operating cost per hour (lines 11 + 13 + 14 + 15)	\$55.50	\$6.00
17. Total operating cost per acre (line 16 ÷ 2.8 acres per hour) ¹³	\$19.80	\$2.14
Total cost		
18. Total cost per hour (line 10 + line 16)	\$81.00	\$15.90
19. Total cost per hour		\$96.90
20. Total cost per acre ¹³ (line 19 ÷ 2.8 acres per hour)		\$34.60

¹Purchase price is the price paid for the machinery, whether new or used.

²The expected ownership period is the years of useful life or the number of years until the machine will be traded. Table 2 lists estimated total hours of useful life for various types of equipment and can be used to estimate the years of useful life if hours of annual use are known. In this example, the tractor is used 500 hours per year and the plow 150 hours.

³Salvage value is the expected selling price or trade-in value of the machine at the end of its ownership period.

⁴Average value: (Purchase price + Salvage value) ÷ 2. This value is often used in machinery cost calculations. However, using this unadjusted average will underestimate the interest charge on capital because it is an end-of-period value. To get a beginning-of-investment-period value, simply add a year of depreciation. The adjusted average formula used in this example is: (Purchase price + Salvage value + Annual depreciation) ÷ 2.

⁵An estimate of annual depreciation should be used. Depreciation is the loss in annual value over the machine's ownership period. Management depreciation (based on years of useful life) rather than tax depreciation (based on the IRS's tax life) should be used. Straight-line depreciation [(Purchase price – Salvage value) ÷ Years of useful life] was used. More complicated depreciation methods can be used, but still will produce only an estimate. Depreciation is known only when the machine is sold or traded.

⁶Interest is an opportunity cost of capital and is charged against the adjusted average value using a real rate of interest. A real (inflation-adjusted) interest rate of 6% was used in the example calculation. Interest should be charged for all capital, not just the borrowed amount.

⁷The charge for taxes, housing, and insurance is based on the values shown in Table 3 (1.1% for tractor and 0.5% for plow) multiplied by the adjusted average value.

⁸Repairs and maintenance costs are based on the repair factor coefficients per \$1,000 of purchase price, which are found in Table 2 (page 7), or (Purchase price ÷ 1,000) x 0.083 (for tractor) and x 0.5 (for plow).

⁹Fuel consumption per hour is based on an engineering equation that relates PTO horsepower to fuel consumption per hour. The factor for diesel is 0.044, and for gasoline it is 0.060. For example, diesel consumption for a 165-hp tractor would be: 165 x 0.044 = 7.25 gallons per hour.

¹⁰Fuel costs per hour are based on the estimated fuel consumption per hour (7.25 gallons) multiplied by the price of off-road diesel (\$3.25 per gallon), or 7.25 gallons per hour x \$3.25 per gallon = \$23.56 per hour. Lubricant costs per hour are estimated using a standard engineering coefficient of 15% of fuel costs, or 0.15 x \$23.56 per hour = \$3.53 per hour. Fuel and lubricant costs: \$23.56 + \$3.53 = \$27.09, rounded to \$27.

¹¹Labor is based on a wage rate of \$16.00 per hour, which includes benefits. This is adjusted by 10% to account for time spent servicing equipment and travel. This converts the cost per hour of labor to a cost per hour of machine operating time. The adjusted labor rate is \$17.60. The appropriate labor adjustment factor will vary by type of operation and travel distances.

¹²When materials (baling twine, seed, chemicals, etc.) are furnished by the custom operator, these costs should be included in the estimate.

¹³A plowing speed that covers 2.8 acres per hour is based on a plow width of 6 feet (18" bottoms), a tractor speed of 4.5 miles per hour, and field efficiency of 85%. These last two factors are the midpoints for the range of values shown in Table 2.

Table 2. Farm machinery field efficiencies, field speeds, hours of useful life, and repair and maintenance factors.

Machine	Field efficiency		Field speed		Estimated life (hr)	Total life R&M cost ¹ (% of list price)	Repair factor/hr ² (per \$1,000 of list price)
	Range (%)	Typical (%)	Range (mph)	Typical (mph)

¹Total R&M cost is the accumulated repair and maintenance cost over the entire useful life as a percentage of the machine's list price.

²The repair factor per hour of use is derived by using the percent of list price for the total life R&M cost from ASAE Standards to calculate the lifetime accumulated repairs per \$1,000 of list price and dividing this value by the total hours of useful life. This method will overestimate repairs and maintenance for machinery owned less than the estimated life. These repair factors were used to estimate repair costs on the tractor and plow in Table 1.

³SP = self-propelled.

Table 3. Percentage of average machine value used to estimate property taxes, housing, and insurance (THI) for selected machinery.

¹Idaho no longer charges property tax on farm machinery. A rate of 1% is often used to estimate property tax in states where it still exists.

²Housing costs can be expressed as a percentage of purchase price, list price, or adjusted average value. Another approach is to estimate the value of the storage area required to place the equipment under cover. First, estimate the number of square feet required to store equipment, multiply this by the cost per square foot to build the storage, and amortize this cost over the machine shed's useful life. The rate depends on the type of shelter. A rate between \$0.75 and \$0.90 per square foot would provide a reasonable estimate based on current construction costs.

³When insurance costs on machinery are unknown, insurance can be estimated using a percentage of purchase price, list price, or adjusted average value. Insurance rates per \$100 of value typically range between 0.4 and 0.6% for most tillage and pull-type harvesting equipment (\$0.40 to \$0.60 per \$100). Rates for tractors and self-propelled machinery are typically higher, ranging between 0.65 and 2.0% (\$0.65 to \$2 per \$100 of value).

Adjusting Custom Rates Using USDA Indices

Custom rates change when costs associated with ownership and operation of farm machinery and equipment change. In the absence of actual market data, a price index can be used to adjust historical custom rates to appropriate current rates based on changes in cost over time. Five individual USDA farm price indices were used to develop a new weighted composite index that can be used for this purpose.

Table 4 shows the individual indices as well as the composite index from 2000 through 2010. As an example, suppose the per-acre cost for moldboard plowing was \$24.00 in 2005. In Table 4, the composite cost index for 2005 is 169, and the composite cost index for 2010 is 213. The adjusted per-acre cost in 2010 would be calculated as follows:

$$213 \div 169 \times \$24.00 = \$30.25$$

The USDA Custom Rates Index is also shown in Table 4. This index tracks the rates farmers paid for custom services reported in the USDA survey. Figure 2 shows annual percentage changes for the composite index and the USDA Custom Rates Index from 2001 to 2010. The composite index rose by 61 percent, from an index value of 132 in 2000 to 213 in 2010, while the

Custom Rates Index increased by only 21 percent, from 120 to 145.

This comparison illustrates the problem faced by custom operators. The composite index tracks how custom operators' costs have changed, while the Custom Rates Index shows how much of the cost increase has been passed on to customers—considerably less than the total cost increase. Cost efficiencies gained from using larger equipment and covering more acres have helped some custom operators deal with this cost-price squeeze, but many have simply been squeezed out of business.

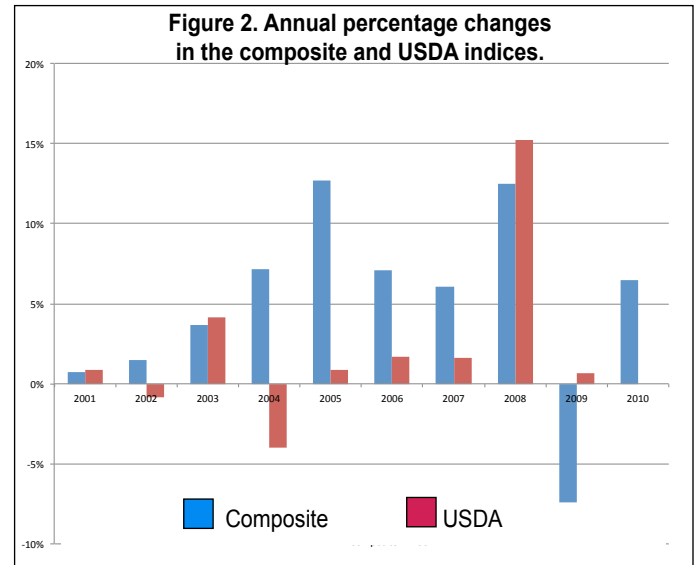

Table 4. USDA indices of prices paid and custom rates, 2000–2010.

Year	Prices paid indices ¹					Composite annual percent change	USDA Custom Rates Index ⁴	Custom rates annual percent change
	Machinery ²	Repairs	Diesel	Wages	Interest			
Weight	0.45	0.10	0.15	0.15	0.15	1.00		
2000	139	125	129	140	113	132	—	120
2001	144	129	121	146	104	133	1%	121
2002	148	132	114	153	100	135	2%	120
2003	151	136	137	157	94	140	4%	125
2004	162	140	165	160	97	150	7%	120
2005	173	146	232	165	113	169	13%	121
2006	182	149	259	171	129	181	7%	123

Source: NASS, USDA Agricultural Prices Annual Summary (various years). Washington, DC, July. <http://usda.mannlib.cornell.edu/MannUsda/viewDocumentInfo.do?documentID=1002>

¹Index values are calculated using 1990–92 as base years, where index values equal 100.

²Machinery index is a composite of tractors, self-propelled, and other machinery.

³The composite custom rate index is calculated by weighting individual component indices as follows: machinery 45%, repairs 10%, diesel 15%, wages 15%, and interest 15%. The calculated value is rounded to the nearest full percentage point. The composite index was developed by the authors and is presented as an alternative to using the USDA Custom Rates Index.

⁴The Custom Rates Index is a USDA-calculated index.

The composite index reflects costs for operators using new equipment. Actual custom rate charges lag behind the composite index at least in part because many custom operators use machinery and equipment purchased in earlier years. Those who use an index as a guide should also be aware that the relative shares of labor, fuel, repair, and machinery costs vary considerably by type of operation. Fuel may account for one-fourth or more of plowing costs, but only 10 percent of a combine's cost. Thus, different weights for machinery, repairs, fuel, and wages may be appropriate.

All indices in Table 4 are based on national cost and price data. Values for Idaho may be slightly different. Data needed to keep these index values current can be obtained from USDA (see "References and Other Useful Links").

Conclusion

Hiring a custom operator provides a reasonable way to accomplish work when time or machinery is lacking. Performing custom work for others can help machine owners make more efficient use of their resources by spreading ownership costs over more acres, reducing the overall operating cost without incurring the expense of acquiring more land.

The survey data provided in this publication should serve only as a guide in setting rates. Prevailing conditions such as weather, field shape and size, the presence of rocks, and other factors affecting ease or difficulty of operation should be considered. For example, some custom operators in irrigated regions charge more for fields with furrow irrigation than for fields with sprinkler irrigation. Rocky or rough field conditions also result in higher charges, especially for tillage and cultivation. The size of the job is another important factor, with higher rates charged for smaller jobs.

Response rates for different types of operations varied widely. In some cases, only a single response was received, so please take this into consideration when using these data. Users should also be aware that quoted rates might not be representative of an entire area or region. For example, fuel costs can be much higher in more remote regions, thus justifying a higher rate.

While custom rates have increased since the last update of this publication in 2005–2006, most rates have not increased as fast as would be indicated by the composite cost index values found in Table 4. These index values suggest custom rates have not kept pace with increases in ownership and operating costs for new equipment.

One cost that does not show up in the appendix tables is the set-up fee charged by a number of custom operators, in addition to the per-unit charges. Fuel prices are another variable that often results in additional charges. Volatile and uncertain fuel prices in recent years left some custom operators losing money if they bid jobs when fuel prices were low and did not include a provision for a fuel surcharge in the contract. Some custom operators have instituted a fuel surcharge, while others require the individual who hires them to provide fuel. Operators in some regions may now offer custom rate quotes minus fuel.

In summary, custom rates need to be configured with as much information as possible, including current market rates in your area. This publication should serve as a data source to help determine equitable yet profitable custom rates for both users and providers of custom services across the major agricultural regions in Idaho.

University of Idaho
Extension

Issued in furtherance of cooperative extension work in agriculture and home economics, Acts of May 8 and June 30, 1914, in cooperation with the U.S. Department of Agriculture, Charlotte V. Eberlein, Director of University of Idaho Extension, University of Idaho, Moscow, Idaho 83844. The University of Idaho provides equal opportunity in education and employment on the basis of race, color, national origin, religion, sex, sexual orientation, age, disability, or status as a disabled veteran or Vietnam-era veteran, as required by state and federal laws.

Published September 2006. Revised September 2011.

\$7.00
